Brouwer Fixed Point Theorem

Exercise 0.1. As per the hint, observe that if $y \in G$, then we have $y = r(y) + (y - r(y))$. Obviously, we have $r(y) \in H$. Moreover, we know that

$$r(y - r(y)) = r(y) - r(r(y)) = 0,$$

and so $y - r(y) \in \ker r$. Thus $G \subseteq H \oplus \ker r$.

The reverse is obviously true, since H and $\ker r$ are both subgroups of G .

Exercise 0.2. Suppose instead that $f : D^1 \rightarrow D^1$ has no fixed point. Then consider the continuous map $g : D^1 \rightarrow S^0$ given by

$$g(x) = \begin{cases} 1 & \text{if } f(x) < x \\ -1 & \text{if } f(x) > x \end{cases}.$$

Notice that because $f(x) \neq x$ for all x , the function g is well-defined.

Moreover, we know that $f(-1) \neq -1$, since f has no fixed point, and so $f(-1) > -1$. Thus $g(-1) = -1$. Similarly, we have $g(1) = 1$.

Thus we have $g(D^1) = S^0$, which is disconnected. This is a contradiction, so f must have had a fixed point.

Exercise 0.3. Suppose that r is such a retract. Then we have the following commutative diagram:

$$\begin{array}{ccc} & S^n & \\ i \nearrow & & \searrow r \\ S^{n-1} & \xrightarrow{1} & S^{n-1} \end{array}$$

Applying H_{n-1} , we get another commutative diagram:

$$\begin{array}{ccc} & H_{n-1}(S^n) & \\ H_{n-1}(i) \nearrow & & \searrow H_{n-1}(r) \\ H_{n-1}(S^{n-1}) & \xrightarrow{H_{n-1}(1)} & H_{n-1}(S^{n-1}) \end{array}$$

We know that $H_{n-1}(S^n) = 0$, however, implying that $H_{n-1}(1) = 0$. This contradicts the fact that $H_{n-1}(S^{n-1}) = \mathbb{Z} \neq 0$. Thus the retraction r could not have existed.

Exercise 0.4. Suppose $g : D^n \rightarrow X$ is a homeomorphism. Then we know that $g^{-1} \circ f \circ g$ is a continuous map from D^n to itself, and so it has a fixed point x . Then we know that $g^{-1}(f(g(x))) = x$, and so it follows that $f(g(x)) = g(x)$. Thus $g(x) \in X$ is a fixed point of f .

Exercise 0.5. Consider the function $h : \mathbb{I} \times \mathbb{I} \rightarrow \mathbb{I} \times \mathbb{I}$ given by

$$h(s, t) = f(s) - g(t) + (s, t).$$

This is the sum of continuous functions, and so it is itself continuous. Moreover, we know that $\mathbb{I} \times \mathbb{I}$ is homeomorphic to D^1 , and so it follows that there is a fixed point (s, t) of h . But this means that $f(s) - g(t) = 0$, and so we are done.

Exercise 0.6. Observe that $x \in \Delta^{n-1}$ must contain some positive coordinate, because $\sum x_i = 1$ and $x_i \geq 0$ for all i . Since $a_{ij} > 0$ for every i, j , it follows that Ax contains only nonnegative coordinates and, moreover, contains at least one positive coordinate. Thus $\sigma(Ax) > 0$, and so $g(x)$ is well-defined.

Moreover, it is continuous because the linear map A , the map σ , and the division function are all continuous.

Because $\Delta^{n-1} \approx D^{n-1}$, it follows that there exists some x with

$$x = \frac{Ax}{\sigma(Ax)}.$$

Then $\lambda = \sigma(Ax) > 0$ is a positive eigenvalue for A and $x \in \Delta^{n-1}$ is a corresponding eigenvector.

We know that x contains only nonnegative coordinates. Suppose then that some coordinate, say x_1 , is zero. Then obviously the first coordinate of λx is zero. However, the first coordinate of Ax is

$$a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n = a_{12}x_2 + \cdots + a_{1n}x_n.$$

Since $\sum x_i = 1$ and $x_1 = 0$, there exists some $k \neq 1$ such that $x_k > 0$. Then $a_{1k}x_k > 0$, and since each i already has $a_{1i}x_i \geq 0$, it follows that the first coordinate of Ax is strictly positive, contradicting that $Ax = \lambda x$.

Thus the eigenvector x has all positive coordinates.

Categories and Functors

Exercise 0.7. We know that

$$g \circ (f \circ h) = g \circ 1_b = g$$

and

$$(g \circ f) \circ h = 1_A \circ h = h,$$

and so associativity implies $g = h$.

Exercise 0.8.

(i) Notice that if 1_A and $1'_A$ are both identities, then we must have

$$1_A = 1_A \circ 1'_A = 1'_A,$$

which proves the desired result.

(ii) If $1'_A$ is the new identity in \mathcal{C}' , then we know that $1'_A \in \text{Hom}_{\mathcal{C}'}(A, A) \subseteq \text{Hom}_{\mathcal{C}}(A, A)$, and so $1_A \circ 1'_A$ is defined. But we know that

$$1'_A \circ 1_A = 1'_A = 1'_A \circ 1'_A,$$

and so Exercise 0.7 implies the result.

Exercise 0.9. Clearly, the Hom-sets are pairwise disjoint, since each i_y^x appears at most once.

It is also obviously associative. In particular, if $a \leq b \leq c \leq d$, then we know that

$$i_d^c \circ (i_c^b \circ i_b^a) = i_d^c \circ i_c^a = i_d^a,$$

and similarly for $(i_d^c \circ i_c^b) \circ i_b^a$.

Finally, the map i_x^x is the identity on $x \in X$. To see that it is a left-identity, note that if $y \leq x$, then

$$i_x^x \circ i_x^y = i_x^y.$$

Similarly, we can show that this map is a right-identity as well, and so we are done.

Exercise 0.10. Disjointness is clear, since there is only one object. Because G is a monoid, it is associative and has an identity, proving that \mathcal{C} is a category.

Exercise 0.11. It is pretty clear that $\text{obj}(\mathbf{Top}) \subset \text{obj}(\mathbf{Top}^2)$. Moreover, a continuous map $f : X \rightarrow Y$ between two topological spaces corresponds to the map (f, \emptyset) in \mathbf{Top}^2 from (X, \emptyset) to (Y, \emptyset) , which then means that \mathbf{Top} can be thought of as a subcategory of \mathbf{Top}^2 .

Exercise 0.12. It is worth noting that Rotman's definition here is incorrect. The morphisms in \mathcal{M} should be the commutative squares, not merely the ordered pairs (h, k) .

Indeed, consider the following counterexample to Rotman's definition. Let \mathcal{C} be the category of sets. Furthermore, let A be a set with more than one element. Then the following diagrams are both commutative:

$$\begin{array}{ccc} A & \xrightarrow{1_A} & A \\ \downarrow 1_A & & \downarrow 0 \\ A & \xrightarrow{0} & \{0\} \end{array} \quad \begin{array}{ccc} A & \xrightarrow{0} & A \\ \downarrow 1_A & & \downarrow 0 \\ A & \xrightarrow{0} & \{0\}. \end{array}$$

This implies that the ordered pair $(1_A, 0)$, where 0 is considered to be the map that sends everything in A to the zero element, is both in $\text{Hom}(1_A, 0)$ and in $\text{Hom}(0, 0)$, contradicting disjointness.

If we instead consider morphisms of \mathcal{M} to be the commutative squares, where composition is defined by “stacking” the squares on top of one another, disjointness is clear. After all, the squares contain f and g , and so Hom-sets of different objects must be disjoint.

Associativity is clear, as the morphisms of \mathcal{C} are associative.

Finally, there is an identity 1_f for every $f \in \text{Hom}_{\mathcal{C}}(A, B)$, namely the one where $h = 1_A$ and $k = 1_B$.

Exercise 0.13. With the hint, this is clear. In particular, we consider \mathbf{Top}^2 to be the subcategory of the arrow category of \mathbf{Top} in which the objects are inclusions, and $\text{Hom}_{\mathbf{Top}^2}(i, j) = \text{Hom}_{\mathbf{Top}}(i, j)$.

Exercise 0.14. To see that it is a congruence at all, observe that Property (i) is satisfied because there is only one Hom-set. Moreover, if $x \sim x'$ and $y \sim y'$, then we know that $x(x')^{-1} = h_x$ and $y(y')^{-1} = h_y$ for some $h_x, h_y \in H$. But then we know that

$$(yx)(y'x')^{-1} = yx(x')^{-1}(y')^{-1} = yh_x(y')^{-1}.$$

However, since $(y')^{-1} = y^{-1}h_y$, we know that this is simply

$$(yx)(y'x')^{-1} = yh_xy^{-1}h_y.$$

Because H is normal, we know that $yh_xy^{-1} \in H$. Thus the product of this and h_y is in H as well, and so $xy \sim x'y'$, as desired.

To see that $[\ast, \ast] = G/H$ simply requires the observation that $x \sim y$ if and only if x and y are in the same coset of H .

Exercise 0.15. This follows from the fact that functors preserve (or, in the case of contravariant functors, reverse) the directions of the arrows. Thus the resulting diagram still commutes.

Exercise 0.16. Note that for (i)–(iv), we can simply use inverses. For instance, for \mathbf{Set} , it suffices to note that if f is a bijection, then f^{-1} is a bijection, which is clearly true. Similarly, the inverse of a homeomorphism is a homeomorphism, and the inverse of a group or ring isomorphism is still an isomorphism.

For (v), note that i_x^y is defined and satisfies the requirements that $i_x^y \circ i_y^x = i_x^x$ and $i_y^x \circ i_x^y = i_y^y$.

For part (vi), notice that f^{-1} works because f is a homeomorphism. In particular, it is a bijection, and so $f^{-1}(A') = A$. Moreover, it is (bi)continuous since f is.

Finally, for the monoid G , if g has a two-sided inverse h , then $hg = gh = 1$, which is the identity element of $\text{Hom}(G, G)$.

Exercise 0.17. To prove that T' is a functor, first observe that criterion (i) of a functor is satisfied because T does so. Moreover, if $[f] \in \text{Hom}_{\mathcal{C}'}(A, B)$, then $f \in \text{Hom}_{\mathcal{C}}(A, B)$, and so $T'([f]) = Tf$ is a morphism in \mathcal{A} . In particular, if $[g] \circ [f] = [g \circ f]$ is defined in \mathcal{C}' , then $g \circ f$ is defined in \mathcal{C} . This means, then, that

$$T'([g] \circ [f]) = T(g \circ f) = (Tg) \circ (Tf) = T'([g]) \circ T'([f]).$$

Finally, it remains to note that $T'([1_A]) = T_{1_A} = 1_{TA} = 1_{T'([A])}$ for every object A . Thus T' is a functor.

Exercise 0.18.

- (i) It is clear that $tG \in \text{obj } \mathbf{Ab}$ for every group G . Now suppose that we have a homomorphism $f : G \rightarrow H$. Then we know that $t(f)$ is a morphism $f|_{tG}$ from tG to tH . To see this, note that it is the restriction of a homomorphism, and thus is itself a homomorphism. Moreover, if $x \in f(tG)$, then $x = f(y)$ for some $y \in G$ with finite order. But then there exists some n so that $y^n = 1$. Thus $x^n = f(y^n) = 1$, and so x has finite order. But $x \in f(G) \subseteq H$ implies that $x \in tH$.

Now we must check that t respects composition. Indeed, if $g \circ f$ is defined, then

$$t(g \circ f) = (g \circ f)_{tG} = g|_{f(tG)} \circ f|_{tG}.$$

But $f(tG) \subseteq tH$, and so this is simply

$$t(g \circ f) = g|_{tH} \circ f|_{tG} = t(g) \circ t(f),$$

which proves that composition is respected.

Finally, note simply that $t(1_G) = 1|_{tG}$, which is the identity on tG .

- (ii) Suppose that f is an injective homomorphism from G to H . Then suppose that $t(f)(x) = t(f)(y)$. But $f(x) = f|_{tG}(x) = t(f)(x)$, and so it follows that $f(x) = f(y)$. Injectivity of f proves the result.
- (iii) Let $G = \mathbb{Z}$ and $H = \mathbb{Z}/2\mathbb{Z}$ and let f take even integers to 0 and odd integers to 1. This is evidently surjective. But $tG = \{0\}$ while $tH = \{0, 1\}$, and so $t(f) : tG \rightarrow tH$ cannot be surjective.

Exercise 0.19.

- (i) If f is a surjection, then consider an arbitrary coset $a + pH$ of H/pH . We know that there exists some $b \in G$ with $f(b) = a$, and so it follows that $F(f)$ takes $b + pG$ to $a + pH$, proving surjectivity of $F(f)$.
- (ii) Consider the function $f : \mathbb{Z} \rightarrow \mathbb{Z}$ taking x to $2x$. Then, letting $p = 2$, we know that $F(f) : \mathbb{Z}/2\mathbb{Z} \rightarrow \mathbb{Z}/2\mathbb{Z}$ has $F(f)([0]) = F(f)([1])$.

Exercise 0.20.

- (i) This is evident because \mathbb{R} is a ring, and the operations are pointwise.
- (ii) By the previous part, we know that if X is a topological space, then $C(X)$ is a ring. Now suppose that $f : X \rightarrow Y$ is a continuous map. Then define

$$\begin{aligned} C(f) : C(Y) &\rightarrow C(X) \\ g &\mapsto g \circ f \end{aligned}$$

and note that this is well-defined. Moreover, we know that $C(g \circ f)(h) = h \circ g \circ f$, while $C(f) \circ C(g)$ takes h to $C(f) \circ (h \circ g) = h \circ g \circ f$, which proves that C reverses composition. Finally, we know that $C(1_x)$ takes g to $g \circ 1_X = g$ and is therefore the identity on $C(Y)$. Thus C (or, rather, the map taking X to $C(X)$, to be precise) gives rise to a contravariant functor.
